

EFFECT OF CPB ON LUNGS

DEEPIKA
Bsc.CPPT

PATHOPHYSIOLOGY OF CPB ON LUNGS

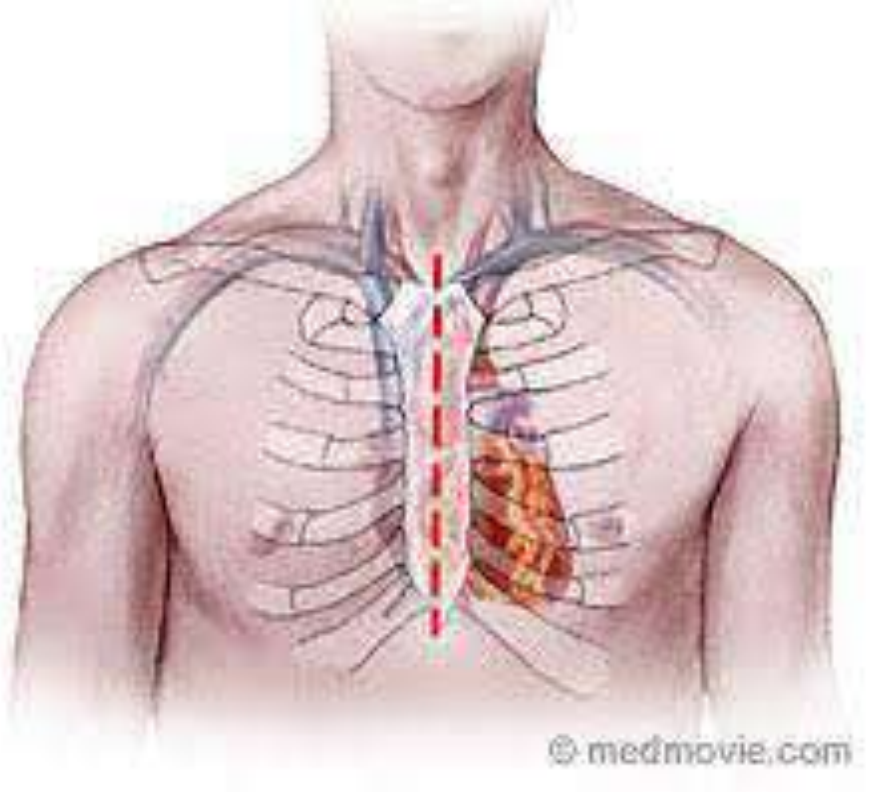

Hemodilution

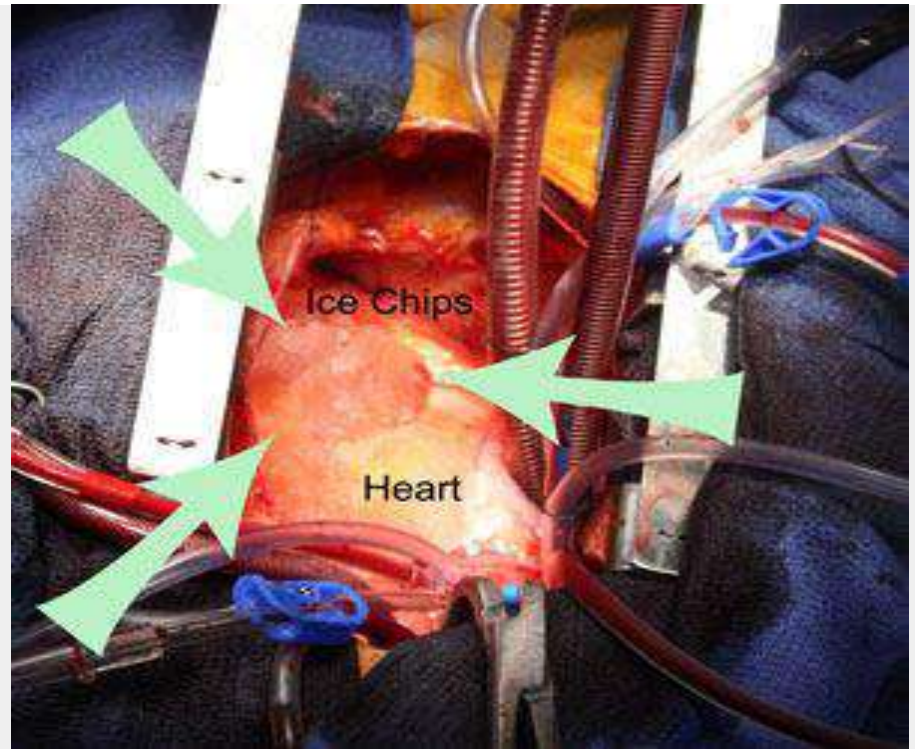

Hypothermia

Contact with artificial surfaces

Cardiac surgery either sternotomy or thoracotomy

Cold solution applied on pericardium

Pt on ventilatory support

Prolonged pump time

PRE-OPERATIVE EFFECTS ON LUNGS

Pt with pre-existing COPD, Asthma

Smoking history

Obesity

Pulmonary edema

Chronic bronchitis

Respiratory sequelae of CPB

A 3D anatomical model of the human lungs, rendered in a reddish-pink color. The model shows the bronchial tree and the lobes of the lungs. The word "ATELECTASIS" is overlaid in large, white, bold, sans-serif capital letters across the center of the image. The background is black, making the reddish-pink lungs stand out.

ATELECTASIS

It is **collapse of a lung or part of a lung(lobe).**

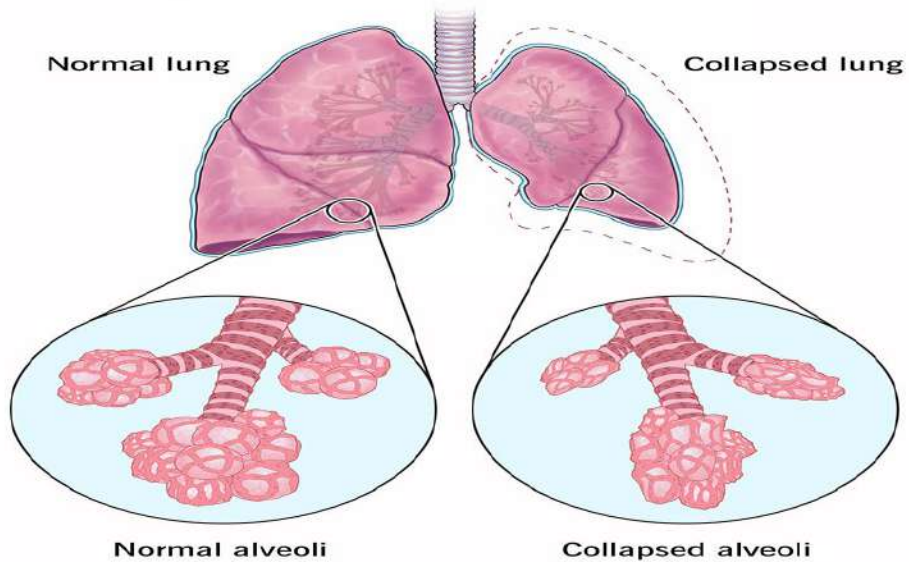

The most common cause of atelectasis is surgery with anesthesia.

The fall in FRC promotes airway closure because of loss of muscle tone.

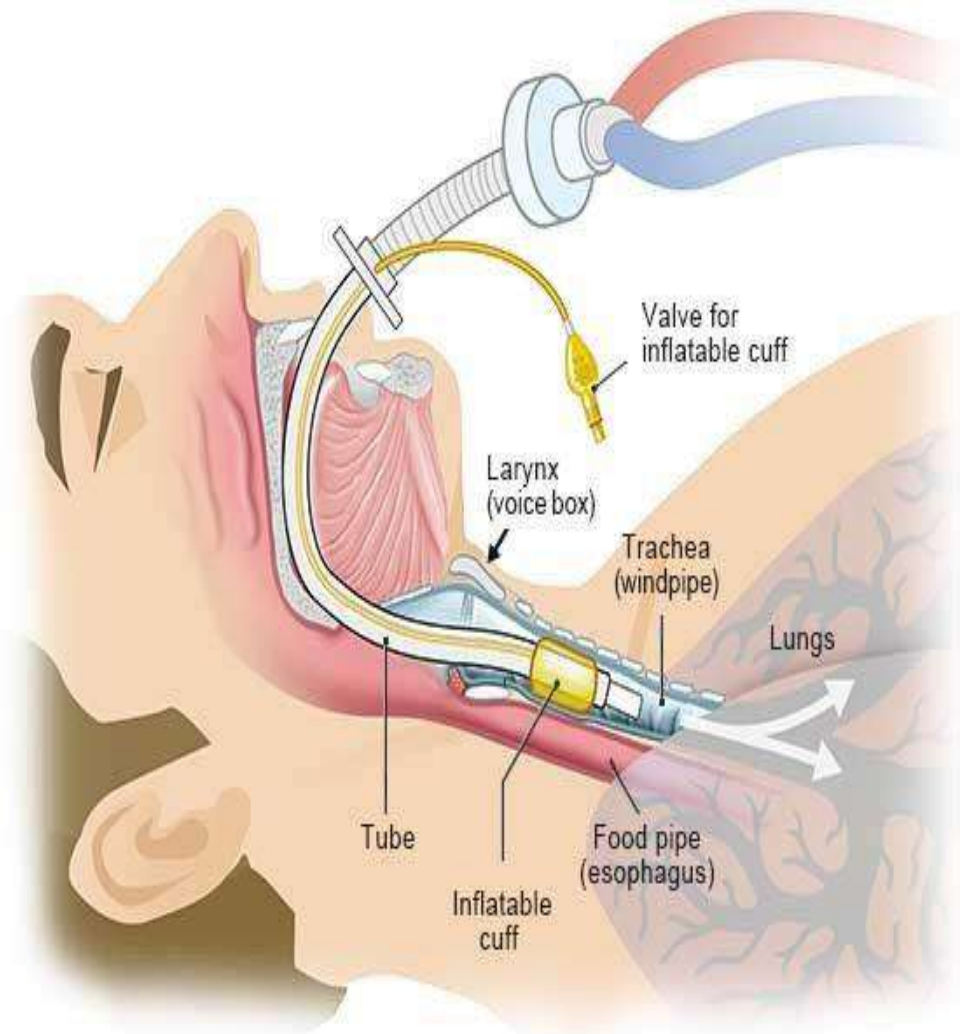

Resorptive atelectasis happens when the O₂ and CO₂ in your alveoli move into your bloodstream and no new air moves in. This causes your alveoli to **collapse**.

Atelectasis

Atelectasis types

Reduced respiratory system compliance

Lungs become more stiff and less able to expand

Increases alveolar distending work of breathing

Increased respiratory system resistance

Airway collapse, fluid accumulation, hypothermia cause bronchoconstriction, reduced compliance, ET tubes, ventilators

ANESTHESIA

After GA and mechanical ventilation initiates atelectasis within 5mins. Relaxed diaphragm distribute gas flow to non-independent region causing "**ventilation-perfusion mismatch**" promotes hypoventilation and microatelectasis of the dependent lung zones.

Surfactant depletion

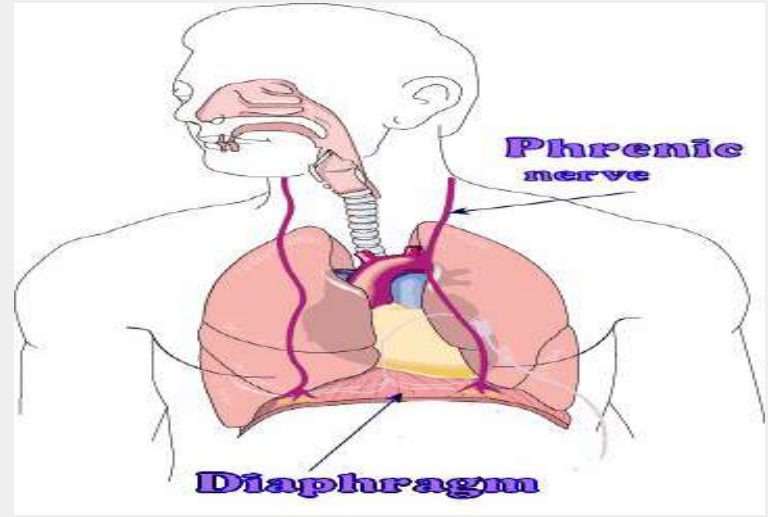

Pulmonary surfactant covers alveolar surface and lowers surface tension to prevent alveolar and small airway collapse.

Exposure to anesthesia reduce surfactant function and increase permeability of alveolar capillary barrier

Atelectasis promotes production proinflammatory cytokines and decrease synthesis of surfactant

Phrenic nerve damage or dysfunction secondary to trauma or extreme cold (ie, exposure to topical slush) may result in significant postoperative loss of lung volume. The "frostbitten phrenic nerve"

A microscopic view of lung tissue, showing a central airway with a thick, pink-stained wall and surrounding alveoli. The alveoli are small, sac-like structures with thin walls, appearing as clusters of small, rounded cells. The overall color is a reddish-pink, typical of stained tissue.

POST OPERATIVE LUNG SYNDROME [PUMP LUNG]

CPB have documented a variety of nonspecific changes including

- patchy atelectasis
 - cellular(endothelial and pneumocytes) swelling and vacuolization
 - Sequestration of leukocytes in association with interstitial edema
 - damage to cellular components
- appear especially with increasing bypass times.

INTRA ALVEOLAR EDEMA

Excessive hemodilution causes accumulation of fluid excessively in alveolar walls and spaces of the lungs.

INTERSTITIAL EDEMA

Increased vascular permeability caused by reduction in colloid osmotic pressure.

Overfilling pulmonary vasculature may cause increased hydrostatic pressure resulting in pulmonary edema

ACUTE RESPIRATORY DISTRESS SYNDROME[ARDS]

Sudden and progressive form **acute lung failure** in alveolar capillary membrane becomes damaged and permeable to intravascular fluid resulting in severe dyspnea, hypoxemia, diffuse pulmonary infiltrates.

Possible Mediators of Lung Injury Associated with CPB

Platelet activation and release of histamine and kallikrein/bradykinin occur during CPB may be important mediators of perioperative inflammation

Bacterial endotoxin (or lipopolysaccharide), a potent stimulator of complement and neutrophils, is released into the circulation during bypass.

STRATEGIES

Administration of **methylprednisolone** before bypass can reduce complement activation.

Glucocorticoids inhibit neutrophil activation induced by endotoxin.

Colloids as pump prime to increase colloid osmotic pressure and reduce edema.

- ❑ **Heparin** bonded circuitry used in reducing the degree of complement activation.
- ❑ **Hemofiltration/ultrafiltration** incorporated aim of reducing pro-inflammatory mediators.
- ❑ **Leukocyte depleting filters** incorporated reducing circulating number of WBC
It has protective effect in reducing severity of lung and myocardial injury post cpb.

Administration Of **APROTININ** serine protease inhibitor decreases platelet dysfunction, lung neutrophil accumulation and adhesion, interleukins thereby decrease lung edema and improve compliance.

volume controlled ventilation with extrinsic maintenance of **PEEP** [positive end expiratory pressure]

A close-up photograph of Barack Obama, the 44th President of the United States, pointing his right index finger directly at the viewer. He is wearing a dark suit, a white shirt, and a red tie. The background is a blue wall with a large, faint white 'S' and 'O' logo. To the left, a portion of the American flag is visible. The image is a meme with white, bold, sans-serif text overlaid.
